

QA Regression Test Summary v3.4

QUALITY ASSURANCE AND REGRESSION TEST SUMMARY

Project: Aegis Core Systems v3.4 Release Candidate Date: August 16, 2026 Prepared by: Elena Rostova, QA Lead

Executive Summary: This report details the findings of the final regression testing cycle for the v3.4 Release Candidate. Testing was conducted over a 72-hour period utilizing our automated Selenium test suite alongside manual exploratory testing for the newly implemented UI components.

Test Coverage and Execution: A total of 1,450 test cases were executed against the staging environment. - Automated Tests: 1,200 - Manual Tests: 250 The overall test execution rate was 100%.

Defect Summary: We identified a total of 14 new defects during this cycle. - Critical: 0 - High: 2 - Medium: 7 - Low: 5

High-Severity Defect Details: 1. BUG-4029: The billing module fails to calculate the updated tier discounts for legacy customers. When a user with a 'Pro' legacy account upgrades to 'Enterprise', the checkout cart displays a NaN error instead of the prorated amount. 2. BUG-4033: OAuth2 login via the Google single sign-on (SSO) integration randomly times out on mobile Safari browsers, leaving the user on a blank authentication screen.

Performance Metrics: API response times remained well within our Service Level Objective (SLO) of <200ms at the 95th percentile under standard load. However, the legacy reporting endpoint spiked to 850ms during concurrent bulk data exports.

Recommendation: Due to the presence of two unresolved High-severity defects, QA recommends delaying the production deployment scheduled for August 18. We advise a hotfix sprint to address BUG-4029 and BUG-4033, followed by a targeted micro-regression test before finalizing the release.
